

ABSTRACT

A CANOpen network including a bus master and an I/O module is disclosed.
5 Each is communicatively coupled to a common bus. The I/O module is subject to a state
change. The bus master collects state information from the I/O module by determining if
the bus master is prepared to receive further data from the bus and sending a trigger
signal from the bus master to the I/O module if the bus master is prepared to receive
further data from the bus. The I/O modules sends a state signal to the bus master in
10 response to the trigger signal.
